

META-ANALYSIS PROCESS FOR EFFECTIVE REVIEWS

Evidence-Synthesis of Literature Review
Data

Dan Stuart, PhD, MLS
TTUHSC – Preston Smith Library
Lubbock, TX 79430

Learning Objectives

- Identify the most crucial parts of executing a literature review and finalizing the literature review process
- Perceiving relevant endpoints and effects measures within relevant studies
- Understanding data extraction and risk of bias assessment
- Using relevant software to create models of approach

Part 1: Finalizing the Literature Review Process

Literature Reviews: The Process

Note that ALL manuscripts must execute a literature review in order to properly evaluate relevant information. A good situated intervention (and, ultimately a successful review project) *will rely on the effectiveness how you execute and document a literature review.*

Literature Review Process

A chief component of major review types such as systematic reviews, scoping reviews, and even rapid reviews is isolating all the best available evidence. This includes:

- Adequate term harvesting and search strategy development
- Translation of a reproducible search strategy across relevant database platforms
- Supplemental searching (hand-searching) within select information resources, and through select methods such as citation analysis
- Deduplication and screening of retrieved records using interrater reliability settings and collective input
- Full-Text review of screened records
- Inclusion of content-aligned records for data extraction and ultimate evidence-synthesis

Clinical Query: How effective is sauna bathing for patients suffering from Cardiovascular Disease?

P – Cardiovascular Disease

I – Sauna Bathing

C – No Comparator

O – Effectiveness

Synonyms and Further Terms

- Cardiology
- Cardiac Events
- Heart Disease
- Steam Bath
- Finnish Bath
- Efficacy
- Treatment Outcome

Search Strategy Development

Further Databases & Strategy Translation

Additional Iterations

- The most relevant research databases are easily identified from the library's homepage
- Manual translations of the official reproducible strategy are generally needed to retrieve all the best available evidence.
- Select tools for automated translation of the strategy are available. Consult your local librarian for further details on this.

Hand Searching and Citation Analysis

Information Resources

- Not all records can be retrieved via a well-constructed reproducible search
- Searching in select web tools with succinct keyword entries is encouraged to gather further evidence.
- Citations and reference lists from foundational articles can retrieve additional records

Citation Analysis

Documenting the Review

- Gathering all the best available evidence requires proper documentation
- Organizing your query, harvested terms, search strategies, iterations, and hand searches is vital for accurately recording your review process
- An Excel or Word document is useful for properly managing your information. Consult a librarian for the best way to do this using Google Sheets.

PICO: In patients with Opioid-Use Disorder, how effective is microdosing Suboxone at diminishing opioid-related withdrawal symptoms?

Records Deduplication

Citation Managers

- Expectedly, many records from one search will appear in a translated, reproduced search on a separate database
- Deduplication is needed to exclude repeat records
- Automated options for this include citation managers and specialized review software

Review Software

Record Screening and Full-Text Review

Screening

- Preliminary screening of all compiled records is generally done by viewing the abstract
- Two or more screeners are required to validate a record's potential
- All successfully screened records should then be evaluated using the full-text.
- Software such as Covidence can effectively organize records for this purpose.

The screenshot displays the Covidence software interface for record screening. At the top, the 'covidence' logo is visible. The main section is titled 'Review Summary' and includes buttons for 'Settings', 'PRISMA', and 'Export'. Below this, the 'Import references' section shows '2 total duplicates removed' and '0 auto-marked as ineligible', with an 'Import' button. The 'Title and abstract screening' section shows '0 irrelevant' and '204 studies to screen'. A 'TEAM PROGRESS' bar is shown with 0 DONE, 0 CONFLICTS, 0 ONE VOTE, and 204 NO VOTES. A 'DANIEL, YOU CAN STILL SCREEN' notification shows '204' studies and a 'Continue' button. A 'Full text review' section shows '0 excluded' and '0 studies to screen'. A 'TEAM PROGRESS' bar is shown with 0 DONE, 0 CONFLICTS, 0 ONE VOTE, and 0 NO VOTES. A notification says 'Daniel, you have not yet started'.

Inclusion for Synthesis

Inclusion Criteria

- Inclusion of relevant records is a delicate process, all the more so because you must sync articles target specific **endpoints and measures of effect**
- Primary and secondary endpoints must need to be addressed by review authors prior to beginning a review, and used to include only the most relevant studies
- Measures of effect, statistical values and metrics associated with endpoints, should likewise be used as markers for inclusion

Endpoints & Effects Measures

Clinical Query: How effective is sauna bathing for patients suffering from Cardiovascular Disease?

- **Potential Endpoints: Mortality and Subsequent Cardiac Episodes (Primary); Quality of Life (Secondary)**
- **Effects Measures: Death Rate and Cardiac Event Rate, LDL Levels, Diastolic and Systolic Blood Pressure, QOL Index**

Study Exclusion

Exclusion Criteria

- Proper review methods will always require that document exclusion reasons
- This means you must report—and even tally—the number of records excluded, and the specific reasons for exclusion
- Covidence enables users to do this effectively within the full-text review folder of all review portals

The screenshot displays the 'Full text review' interface in the Covidence system. At the top, there is a search bar and a 'Bulk upload missing full texts' button. Below this, a navigation bar shows 'Screen references 12', 'Resolve conflicts 0', 'Awaiting other reviewer 0', and 'Excluded references 0'. The main content area features a list of studies, with the first one selected. The study details include the title 'i-Therapy: Asynchronous Telehealth Expands Access to Mental Health Care and Challenges Tenets of the Therapeutic Process', authors 'Myers, K.; Vander Stoep, A.', journal information 'J Am Acad Child Adolesc Psychiatry Jan 2017;56(1):5-7', and DOI '10.1016/j.jaac.2016.11.001'. There are buttons for 'Download PDF' and 'Upload full text'. A dropdown menu is open, asking 'What is the reason for excluding this study?' and listing various reasons such as 'Wrong study design', 'Wrong setting', 'Wrong route of administration', 'Wrong patient population', 'Wrong outcomes', 'Wrong intervention', 'Wrong indication', 'Wrong dose', 'Wrong comparator', 'Paediatric population', and 'Adult population'. An 'Exclude' button is visible at the bottom right of the dropdown menu.

Study Types For Inclusion

Randomized Controlled Trial

Abstract

Regular exercise and sauna bathing have each been shown to improve cardiovascular function in clinical populations. However, experimental data on the cardiovascular adaptations to regular exercise in conjunction with sauna bathing in the general population are lacking. Therefore, we compared the effects of exercise and sauna bathing to regular exercise using a multi-arm randomized controlled trial. Participants ($n = 47$) aged 49 ± 9 with low physical activity levels and at least one traditional cardiovascular disease (CVD) risk factor were randomly assigned (1:1:1) to guideline-based regular exercise and 15-min postexercise sauna (EXE), guideline-based regular exercise (EXE) or control (CON) for 8 wk. The primary outcomes were blood pressure (BP) and cardiorespiratory fitness (CRF). Secondary outcomes included fat mass, total cholesterol levels, and arterial stiffness. EXE had a greater change in CRF ($+6.2$ mL/kg/min; 95% CI, $+4.2$ to $+8.3$ mL/kg/min) and fat mass but no differences in BP when compared with CON. EXS displayed greater change in CRF ($+2.7$ mL/kg/min; 95% CI, $+0.2$ to $+5.3$ mL/kg/min), lower systolic BP (-8.0 mmHg; 95% CI, -14.6 to -1.4 mmHg), and lower total cholesterol levels compared with EXE. Regular exercise improved CRF and body composition in sedentary adults with CVD risk factors. However, when combined with exercise, sauna bathing demonstrated a substantially supplementary effect on CRF, systolic BP, and total cholesterol levels. Sauna bathing is a valuable lifestyle tool that complements exercise for improving CRF and decreasing systolic BP. Future research should focus on the duration and frequency of exposure to ascertain the dose-response relationship.

For systematic reviews that aim to incorporate a meta-analysis component, always target prospective, controlled studies for inclusion

Prioritize trial studies, chiefly randomized controlled trial, investigating the intervention for the predetermined endpoints and effects measures

Randomized Controlled Trial

Abstract

Regular Finnish sauna use is associated with a reduced risk of cardiovascular mortality. However, physiological mechanisms underlying this association remain unknown. This study determined if an 8-wk Finnish sauna intervention improves peripheral endothelial function, microvascular function, central arterial stiffness, and blood pressure in adults with coronary artery disease (CAD). Forty-one adults (62 ± 6 yr, 33 men/8 women) with stable CAD were randomized to 8 wk of Finnish sauna use ($n = 21$, 4 sessions/wk, 20-30 min/session, 79°C, 13% relative humidity) or a control intervention ($n = 20$, lifestyle maintenance). Brachial artery flow-mediated dilation (FMD), carotid-femoral pulse wave velocity (cf-PWV), total (area under the curve) and peak postocclusion forearm reactive hyperemia, and blood pressure (automated auscultation) were measured before and after the intervention. After the sauna intervention, resting core temperature was lower (-0.27°C [-0.54 , -0.01], $P = 0.046$) and sweat rate during sauna exposure was greater (0.3 L/h [0.1 , 0.5], $P = 0.003$). The change in brachial artery FMD did not differ between interventions (control: 0.07% [-0.99 , $+1.14$] vs. sauna: 0.15% [-0.89 , $+1.19$], interaction $P = 0.909$). The change in total ($P = 0.031$) and peak ($P = 0.024$) reactive hyperemia differed between interventions due to a nonsignificant decrease in response to the sauna intervention and an increase in response to control. The change in cf-PWV ($P = 0.816$), systolic ($P = 0.951$), and diastolic ($P = 0.292$) blood pressure did not differ between interventions. These results demonstrate that four sessions of Finnish sauna bathing per week for 8 wk does not improve markers of vascular health in adults with stable CAD. **NEW & NOTEWORTHY** This study determined if unsupervised Finnish sauna bathing for 8 wk improves markers of vascular health in adults with coronary artery disease. Finnish sauna bathing reduced resting core temperature and improved sweating capacity, indicative of heat acclimation. Despite evidence of heat acclimation, Finnish sauna bathing did not improve markers of endothelial function, microvascular function, arterial stiffness, or blood pressure.

Further Study Types For Inclusion

If the compiled search and screening process reveals that no trial data meets the criteria, see if any further prospective, observational studies are available.

While not always specified, prospective data will often be assessed using a cohort study design

Abstract

Importance: Sauna bathing is a health habit associated with better hemodynamic function; however, the association of sauna bathing with cardiovascular and all-cause mortality is not known.

Objective: To investigate the association of frequency and duration of sauna bathing with the risk of sudden cardiac death (SCD), fatal coronary heart disease (CHD), fatal cardiovascular disease (CVD), and all-cause mortality.

Design, setting, and participants: We performed a prospective cohort study (Finnish Kuopio Ischemic Heart Disease Risk Factor Study) of a population-based sample of 295 middle-aged (age range, 42-60 years) men from Eastern Finland. Baseline examinations were conducted from March 1, 1984, through December 31, 1989.

Exposures: Frequency and duration of sauna bathing assessed at baseline.

Results: During a median follow-up of 20.7 years (interquartile range, 18.1-22.6 years), 190 SCDs, 281 fatal CHDs, 407 fatal CVDs, and 929 all-cause mortality events occurred. A total of 601, 1513, and 201 participants reported having a sauna bathing session 1 time per week, 2 to 3 times per week, and 4 to 7 times per week, respectively. The numbers (percentages) of SCDs were 61 (10.1%), 119 (7.8%), and 10 (5.0%) in the 3 groups of the frequency of sauna bathing. The respective numbers were 89 (14.9%), 175 (11.5%), and 17 (8.5%) for fatal CHDs; 134 (22.3%), 249 (16.4%), and 24 (12.0%) for fatal CVDs; and 295 (49.1%), 572 (37.8%), and 62 (30.8%) for all-cause mortality events. After adjustment for CVD risk factors, compared with men with 1 sauna bathing session per week, the hazard ratio of SCD was 0.78 (95% CI, 0.57-1.07) for 2 to 3 sauna bathing sessions per week and 0.37 (95% CI, 0.18-0.75) for 4 to 7 sauna bathing sessions per week (P for trend = .005). Similar associations were found with CHD, CVD, and all-cause mortality (P for trend ≤.005). Compared with men having a sauna bathing session of less than 11 minutes, the adjusted hazard ratio for SCD was 0.93 (95% CI, 0.67-1.28) for sauna bathing sessions of 11 to 19 minutes and 0.48 (95% CI, 0.31-0.75) for sessions lasting more than 19 minutes (P for trend = .002); significant inverse associations were also observed for fatal CHDs and fatal CVDs (P for trend ≤.03) but not for all-cause mortality events.

Conclusions and relevance: Increased frequency of sauna bathing is associated with a reduced risk of SCD, CHD, CVD, and all-cause mortality. Further studies are warranted to establish the potential mechanism that links sauna bathing and cardiovascular health.

Abstract

Background: Sauna bathing is associated with reduced cardiovascular risk, but the mechanisms underlying this beneficial effect are not entirely understood. We aimed to assess the relationship between sauna bathing and risk of incident hypertension.

Methods: Frequency of sauna bathing was ascertained using questionnaires in the Kuopio Ischemic Heart Disease Study, a prospective cohort study conducted in Eastern Finland that comprised a population-based sample of 1,021 men aged 42 to 60 years without hypertension at baseline. The incidence of hypertension was defined as a physician diagnosis of hypertension, systolic blood pressure (SBP) >140 mm Hg, diastolic blood pressure >90 mm Hg, or use of antihypertensive medication.

Results: During a median follow-up of 24.7 years, 251 incident cases (15.5%) were recorded. In Cox regression analysis adjusted for baseline age, smoking, body mass index, and SBP; compared to participants reporting 1 sauna session per week, the hazard ratio for incident hypertension in participants reporting 2 to 3 sessions and 4 to 7 sessions was 0.76 (95% confidence interval: 0.57-1.02 and 0.54 (0.32-0.91), respectively. The corresponding hazard ratios were similar after further adjustment for glucose, creatinine, alcohol consumption, heart rate, family history of hypertension, socioeconomic status, and cardiorespiratory fitness: 0.83 (95% confidence interval: 0.59-1.18) and 0.53 (0.28-0.98), respectively.

Conclusions: Regular sauna bathing is associated with reduced risk of hypertension, which may be a mechanism underlying the decreased cardiovascular risk associated with sauna use. Further epidemiological and experimental studies could help elucidate the effects of sauna bathing on cardiovascular function.

Keywords: Sauna bathing; blood pressure; cohort; hypertension; prevention.

Risk of Bias Assessment

Risk of Bias

- Accounting for the risk of bias within included studies is essential for all serious review types—and vital for systematic reviews with meta-analyses.
- Bias can arise from different sources. Collectively evaluating studies for such biases can help justify reasons for inclusion and better articulate the assessed, synthesized results

Types of Bias

- Publication Bias
- Selection Bias
- Reporting Bias
- Recall Bias
- Sampling Bias

Screening for Risk of Bias

Risk of Bias

- Screening trial and prospective study data will require that you rate things like allocation, blinding and sequence generation in line with reporting guidelines
- Just as with preliminary record screening, full-text review, and final inclusion, screening for bias should be done by two or more rating appraisers
- Software such as Covidence can enable users to do this more effectively.

The screenshot displays the Covidence web interface. At the top, the 'covidence' logo and 'Mock_MIDS' project name are visible. A search bar contains 'Search studies'. Below this, the 'Extraction' view shows a summary: 'Total included 6', 'Not started 6', 'In progress 0', 'Consensus required 0', and 'Complete 0'. An 'Export' button is present. A list of studies is shown, with one selected: '#1442 - Joshi 2021' by Joshi, C. N.; Yang, M. L.; Eschbach, K.; Tong, S.; Jacobson, M. P.; Stillman, C.; Kropp, A. E.; Shea, S. A.; Frunzi, G. M.; Thomas, J. F.; Olson, C. A. Below this, the 'Quality Assessment Template' editor is open, showing a 'Draft' status. The editor is divided into three panels: 'ITEM SETTINGS', 'EDITOR', and 'PREVIEW'. The 'EDITOR' panel shows a text box with the placeholder 'I want to start from scratch' and three items for rating: 'Sequence generation', 'Allocation concealment', and 'Blinding of participants and personnel'. Each item has a dropdown menu with options for 'High', 'Low', and 'Unsure'. The 'PREVIEW' panel shows the 'Sequence generation' and 'Allocation concealment' sections with their respective descriptions and rating options.

Collective Bias Assessment

Risk of Bias

- Screening for bias must be done collectively with reference to the full text, with consensus ratings always needed.
- Bias templates include options for perusing the full-text content while rating using appropriate interrater reliability indexes (ex. High, Medium, Low)

The screenshot shows a web interface for a research article. At the top right, there are two buttons: 'Save' and 'Send for Consensus', with the latter highlighted by a red box. The article title is 'Finnish sauna bathing and vascular health of adults with coronary artery disease: a randomized controlled trial'. The authors listed are Amélie Debray, Hugo Gravel, Laurence Garceau, Audrey-Ann Bartlett, Georgia K. Chaseling, Hadiatou Barry, Parya Behzadi, Nicholas Ravanelli, Josep Iglesias-Grau, Anil Nigam, Martin Juneau, and Daniel Gagnon. The abstract discusses the effects of Finnish sauna use on cardiovascular health in adults with CAD. The sidebar on the right is titled 'QUALITY ASSESSMENT' and contains two sections: 'Sequence generation' and 'Allocation concealment'. Each section has a rating scale with options for High, Low, and Unsure, and a text input field for supporting text.

Data Extraction

Extracting Relevant Data

- Once the included studies are assessed for validity and risk of bias, it's time to extract the relevant data based on endpoints and effects measures
- This would include creating templates for and relevant outcome tables for evaluation. Covidence can help with this process as well

The screenshot shows the 'Data Extraction Template' editor in 'Draft' mode. The interface is divided into three main sections: 'ITEM SETTINGS', 'EDITOR', and 'PREVIEW'. The 'EDITOR' section is active, showing a list of items to be extracted. The 'PREVIEW' section shows the layout of the extracted data.

Data Extraction Screening

Extracting Relevant Data

- Use a recommended template or a customized tabular arrangement to record data from the full text.
- Generally, all raters must contribute to extraction. This means cross-checking that other raters have entered the correct data.

ACEI, angiotensin-converting enzyme inhibitors; ARA, angiotensin receptor antagonists; B, black individual; BMI, body mass index; C, Caucasian individual; CABG, coronary artery bypass graft; DBP, diastolic blood pressure; HR, heart rate; HbA1c, glycated hemoglobin A1C; HDL, high-density lipoprotein; H, hispanic individual; LDL, low-density lipoprotein; MVPA, moderate to vigorous physical activity; MI, myocardial infarction; PCI, percutaneous coronary intervention; SBP, systolic blood pressure; TC, total cholesterol. Data are presented means ± standard deviation or n (%), and mean difference (95% confidence interval). P value for PRE is from an independent t test comparing control and sauna at baseline. P value for interaction is from an intervention × time interaction × time interaction of a mixed-effects model. *Other vasodilators include nitroglycerin and hydralazine.
